

High pressure Shock-wave compression

Ulf Zastra, ^{1,*} for the entire HED-HIBEF team at the European XFEL

¹*European XFEL, Schenefeld, Germany*

*E-mail: ulf.zastra@xfel.eu

The advent of the first X-ray free-electron lasers (XFELs), FLASH in 2004 and LCLS in 2009, may prove to be the most profound development since the invention of the laser and, equally, the synchrotron. Sharp improvements in a number of laser parameters, most notably intensity and pulse duration, support this expectation. This brings scientific dreams within reach. Indeed, the unprecedented opportunities and expectations have triggered considerable research activities worldwide. In my talk, I will give an overview of the experimental application of the European XFEL to explore relativistic laser plasma interactions, warm dense matter, materials in extreme conditions, and laboratory astrophysics.

Since May 2019, the High Energy Density Science (HED) instrument at the European X-ray Free-Electron Laser Facility in Schenefeld, Germany, allows international users to investigate a wide range of materials and systems at extreme conditions [1]. European XFEL and the HIBEF user consortium [2] form a joint group of more than 40 people for HED research, development and user operation.

To drive a sample from ambient conditions to extreme excitations, a variety of high energy drivers are available. In particular, we have three separate optical laser systems for warm- to hot-dense-matter creation, dynamic compression and laser-plasma interaction in electron-relativistic regime. These drivers allow studying various phase space parameters with time-resolution down to 10 fs, pressures into the TPa regime, and electric field strength up to 1021 W/cm, both at surfaces and in the bulk.

The unique HED instrument allows to study these systems with precise ultrafast x-ray probes including spectroscopy, x-ray diffraction, small- and wide-angle scattering as well as phase contrast imaging methods. It is fully tunable in the photon energy range from 5 to 25 keV at different bandwidths, can be focused to a variety of diameters.

This talk will cover the scientific agenda, techniques and capabilities of the HED-HIBEF instrument with special emphasis on dynamically compressed matter with nanosecond lasers launching shock waves. I will present selected scientific highlights demonstrating our capabilities.
