- Deep meson production: a key channel for GPDs extractions
- "Golden objective": combined DVCS & DVMP extraction
- Possibility to do this at NLO ?

Difficulty 1

Effects of the choice of the DA for this kind of extraction ?

Difficulty 2

At NLO, possible scheme/scale effects (canonical choice vs. BLM choice)?

Pragmatic approach

Gather as much information from any side, and make "reasonable" assumptions

비로 서로에 수전

Recent models and calculations of PDA

- Dyson-Schwinger techniques:
 - Multiple meson can be addressed
 - ★ Pion DA (leading and sub-leading twist)
 - *ρ*-meson DA (leading twist)
 - ★ J/Ψ DA (leading twist)
 - Many Mellin moments can be computed
 - Interaction is approximated
 - Computation of the gauge link remains to be addressed (although claimed to be small in the case of DA)
- Lattice QCD computations
 - Precise computations of the first non-trivial Mellin Moment
 - x dependence with LaMET but with wide errors
- Possible parametrisations combining information from the two ?

▲ 글 ▶ _ 글| 글

Bethe-Salpeter Equation

• Two-body bound states obey their own equation called the Bethe-Sapeter equation:

- It is needed to approximate K consistently the quark propagator used to fulfil QCD symmetries (especially the Axial-Vector Ward-Takahashi Identities)
- The DA is given by projecting the Bethe-Salpeter wave function:

$$\varphi(\mathbf{x}) \propto \int \frac{\mathrm{d}^4 k}{(2\pi)^4} \delta\left(\mathbf{x} - \frac{k \cdot n}{P \cdot n}\right) \chi(k, P)$$

• Advantages and Drawbacks

Lattice QCD Moments for the pion

• Lattice can compute local operators related to $\langle \xi^m \rangle$:

$$\langle \xi^m \rangle(\mu) = \int \mathrm{d}x (2x-1)^m \varphi(x,\mu)$$

• Calculation possible for m = 2, beyond operator mixing makes it difficult

$$\langle \xi^2
angle^{MS}(\mu = 2 \text{GeV}) = 0.2361(41)(39)(?)$$

V. Braun et al., Phys.Rev. D92 (2015) no.1, 014504

• Preliminary results shown at ECT* workshop last September for $\langle \xi^2 \rangle$ at physical point and in the continuum limit, but with renormalisation to be finalised:

$$\langle \xi^2 \rangle^{\overline{\mathrm{MS}}}(\mu = 2 \mathrm{GeV}) = 0.2399(64)$$

G. Bali, talk at "Mapping PDF and PDA", ECT*, September 10-14, 2018

Parametrisations

Assumptions

1) DSE + LaMET \rightarrow broad unimodal DA is favoured over bimodal one 2) Lattice computation of $\langle \xi^2 \rangle$ is reliable

Asymptotic DA

$$\varphi_{As}(x) = 6x(1-x)$$

• Logarithmic DA (one parameter κ fitted on lattice data)

$$arphi_{\mathsf{ln}}(x) \propto 1 - rac{\mathsf{ln}\left[1 + \kappa x(1-x)
ight]}{\kappa x(1-x)}$$

• Power DA (one parameter ν fitted on lattice data)

$$arphi_
u(x) \propto x^
u(1-x)^
u$$

Square root DA

$$\varphi_{1/2}(x) \propto \sqrt{x(1-x)}$$

• A specific algebraic parametrisation of LFWF was introduced by D. Mueller and D. Hwang

D. Müller and D. Hwang PLB 660 (2008) 350-359

January 24th, 2019

18 / 30

- After computing the DGLAP (or outer) region, it was possible to obtain the DD by using a clever change of variable
- This allows the computations in the ERBL region (up to a D-term).

Question

How general is the procedure? Can it be done for any LFWFs?

DAs and GPDs

Radon Transform and GPDs

• We can define a *D*-term such that:

$$\int_{-1}^{1} \mathrm{d}x \, x^{m} \left(H(x,\xi) - D(x/\xi) \right) = \sum_{i \text{ even}}^{m} (2\xi)^{i} C_{m,i},$$

yielding the Ludwig-Helgason consistency conditions.

• From Hertle theorem (1983), we know that H - D is in the range of the Radon transform and that:

$$H(x,\xi) = D(x/\xi) + \int_{\Omega} d\beta d\alpha \delta(x - \beta - \alpha \xi) F_{D}(\beta, \alpha)$$

This allows us to identify the DD F_D with the Radon transform of H - D. This has been first noticed by O. Teryaev (PLB510 2001 125).

• It should be possible to use the **limited** Radon inverse transform to obtain the DD and thus the ERBL part.

물 이 제품 이 문제로

Radon Transform and GPDs

• We can define a *D*-term such that:

$$\int_{-1}^{1} \mathrm{d}x \, x^{m} \left(H(x,\xi) - D(x/\xi) \right) = \sum_{i \text{ even}}^{m} (2\xi)^{i} C_{m,i},$$

yielding the Ludwig-Helgason consistency conditions.

• From Hertle theorem (1983), we know that H - D is in the range of the Radon transform and that:

$$H(x,\xi) = D(x/\xi) + \int_{\Omega} d\beta d\alpha \delta(x - \beta - \alpha \xi) F_{D}(\beta, \alpha)$$

This allows us to identify the DD F_D with the Radon transform of H - D. This has been first noticed by O. Teryaev (PLB510 2001 125).

• It should be possible to use the **limited** Radon inverse transform to obtain the DD and thus the ERBL part.

NB: This is equivalent to fixing the DD to the Polyakov-Weiss scheme. The same argument can be done in other schemes, but the D-term remains ambiguous.

DAs and GPDs

Uniqueness of the Extension

 $H(x,\xi)=0\quad {\rm for}\quad (x,\xi)\in {\rm DGLAP}\Rightarrow F_{\mathcal{D}}(\beta,\alpha)=0\quad {\rm for \ all}\quad (\beta\neq 0,\alpha)\in \Omega$

Boman and Todd-Quinto, Duke Math. J. 55, 943 (1987)

insuring the uniqueness of the extension up to D-term like terms.

• The DGLAP region almost completely characterises the entire GPD.

New modeling strategy

- Compute the DGLAP region through overlap of LFWFs
 ⇒ fulfilment of the positivity property
- Extension to the ERBL region using the Radon inverse transform
 fulfilment of the polynomiality property

An algebraic model for the Pion BSWF

• Consider the Euclidean Bethe-Salpeter Wave Function based on the Nakanishi representation:

$$\Psi(k,P) = S(k-P/2)\Gamma(k,P)S(k+P/2)$$
$$S(k) = \frac{i\gamma \cdot k + M}{k^2 + M^2} \qquad \Gamma(k,P) = iN\gamma_5 \int_{-1}^{1} \frac{\mathrm{d}z(1-z^2)M^2}{\left[\left(k - \frac{1-z}{2}P\right)^2 + M^2\right]}$$

January 24th, 2019

▶ ▲ 글 ▶ _ 글 날

An algebraic model for the Pion BSWF

 Consider the Euclidean Bethe-Salpeter Wave Function based on the Nakanishi representation:

$$\Psi(k,P) = S(k-P/2)\Gamma(k,P)S(k+P/2)$$

(k) = $\frac{i\gamma \cdot k + M}{k^2 + M^2}$ $\Gamma(k,P) = iN\gamma_5 \int_{-1}^{1} \frac{\mathrm{d}z(1-z^2)M^2}{\left[\left(k - \frac{1-z}{2}P\right)^2 + M^2\right]}$

• We can compute from it the 2-body LFWFs:

$$\Phi_{\uparrow\downarrow}(x, \mathbf{k}_{\perp}) = 8\sqrt{15} \pi \frac{M^3}{(\mathbf{k}_{\perp}^2 + M^2)^2} (1 - x) x \Phi_{\uparrow\uparrow}(x, \mathbf{k}_{\perp}) = -8i\sqrt{15} \pi \frac{M^2}{(\mathbf{k}_{\perp}^2 + M^2)^2} (1 - x) x$$

An algebraic model for the Pion BSWF

 Consider the Euclidean Bethe-Salpeter Wave Function based on the Nakanishi representation:

$$\Psi(k,P) = S(k-P/2)\Gamma(k,P)S(k+P/2)$$

$$S(k) = \frac{i\gamma \cdot k + M}{k^2 + M^2} \qquad \Gamma(k, P) = iN\gamma_5 \int_{-1}^1 \frac{\mathrm{d}z(1 - z^2)M^2}{\left[\left(k - \frac{1-z}{2}P\right)^2 + M^2\right]}$$

• We can compute from it the 2-body LFWFs:

$$\begin{split} \Phi_{\uparrow\downarrow}(x,\mathbf{k}_{\perp}) &= 8\sqrt{15} \pi \, \frac{M^3}{\left(\mathbf{k}_{\perp}^2 + M^2\right)^2} \, \left(1 - x\right) x \\ \Phi_{\uparrow\uparrow}(x,\mathbf{k}_{\perp}) &= -8i\sqrt{15} \pi \, \frac{M^2}{\left(\mathbf{k}_{\perp}^2 + M^2\right)^2} \, \left(1 - x\right) x \end{split}$$

Nakanishi Representation

The present model is very simple, but the Nakanishi formalism is general, and can be straigthforwardly apply to more complicated models.

Few comments

- Simple LFWFs yield quite complicated GPDs in the DGLAP region;
- Yet algebraic results can be obtained both for the DD and the GPD in the ERBL region;
- Provide us with a benchmarck for numerical approaches

Cédric Mezrag (INFN)

DAs and GPDs

Numerical Inversion

• For more complicated LFWFs, algebraic inversion is not possible, we need to develop a **systematic** numerical method to handle it.

- Difficulty: The limited inverse Radon transform is a severely ill-posed problem in the sens of Hadamard.

▶ ▲ 문 ▶ . 프 님

Numerical Inversion

- For more complicated LFWFs, algebraic inversion is not possible, we need to develop a **systematic** numerical method to handle it.
- Difficulty: The limited inverse Radon transform is a severely ill-posed problem in the sens of Hadamard.
- Using finite element analysis we obtained:

Modeling through LFWF

- We have now a generic technique to model GPDs from LFWFs guaranteeing both positivity and polynomiality.
- PARTONS allows us to go from LFWFs up to the DVCS observables.
- The question of building a model based on effective LFWFs can be addressed
- Advantages:
 - Fulfil all properties by construction
 - Bridges with other hadron physics communities (?)
- Drawbacks: hole at $x = \xi$ kinematics due to LFWF being *zero* at their edges.
 - filled by evolution (?)
 - effective LFWFs not vanishing at the edges (?)
 - specific $x = \xi$ physics (?)

Conclusion

Modeling DA

- Progresses have been done on the theory side
- Theoretical calculations seem to favour the broad unimodal DA
- Is it compatible with phenomenology (?)
- Would help extraction of GPDs from DVMP

Modeling GPDs

- New modeling approach based on LFWFs
- Fulfil all theoretical constraints
- Is it compatible with phenomenology (?)
- Use for global GPD fit and beyond (?)

Thank you for your attention

Algebraic Inversion

$$\begin{split} H(x,\xi,t) &= (1-x)\int_{\Omega} d\beta d\alpha \delta(x-\beta-\alpha\xi)h_P(\beta,\alpha,t) \\ h_P(\beta,\alpha,t) &= \frac{15}{2}\theta(\beta)\left[1+\frac{-t}{4M^2}\left((1-\beta)^2-\alpha^2\right)\right]^{-3} \\ &\times \left[1-3(\alpha^2-\beta^2)-2\beta+\frac{-t}{4M^2}\left(1-(\alpha^2-\beta^2)^2-4\beta(1-\beta)\right)\right], \end{split}$$

From the algebraic DD we can deduce the GPD in ERBL region

$$H(x,\xi,0)|_{|x|\leq\xi} = \frac{15}{2} \frac{(1-x)(\xi^2-x^2)}{\xi^3(1+\xi)^2} \left(x+2x\xi+\xi^2\right) ,$$

DAs and GPDs

► Ξ Ξ.

Numerical Basis

- Use of a P_1 (planar by pieces) basis
- We have to trade of precision and noise: In ill-posed inverse problem, small errors coming from our discretisations can trigger significant increases in the numerical noise.
